## Declaration

---

I Sarthak Pandit, student of B.Tech - CSE at JK Lakshmipat University, hereby declare that the Major Capstone Project titled “ Customer Churn Prediction Using Custom Logistic Regression” submitted as part of the LaunchED Global Machine Learning Internship Program is my own original work.

I further declare that:

This project has not been submitted elsewhere for any academic or professional purpose.

All sources of information and references have been duly acknowledged.

The model implementation using NumPy was coded independently without copying from any existing codebase.

All data used in this project is publicly available (IBM Telco Customer Churn dataset).

Name: Sarthak Pandit

Signature: 

Date: 31 May 2026

## Acknowledgement

---

I would like to express my sincere gratitude to LaunchED Global for providing me with this excellent internship opportunity in the domain of Machine Learning. The structured curriculum, real-world project exposure, and consistent mentorship throughout the program have been invaluable in shaping my technical understanding.

I am thankful to the entire LaunchED support team for their prompt assistance and guidance at every step of the internship, from onboarding to capstone submission.

Finally, I thank IBM for making the Telco Customer Churn dataset publicly available, which served as the foundation for this project.

Sarthak Pandit

JK Lakshmipat University

## Abstract

---

Customer churn—the phenomenon where subscribers cancel their service—represents a critical business challenge for telecom companies worldwide. Acquiring a new customer costs 5 to 7 times more than retaining an existing one, making early churn prediction a high-value machine learning application.

This project presents the design, implementation, and evaluation of a Logistic Regression classifier built entirely from scratch using NumPy, trained on the IBM Telco Customer Churn dataset comprising 7,043 customers and 20 features. The implementation covers all core mathematical components: numerically stable sigmoid activation, weighted binary cross-entropy loss for class imbalance handling, mini-batch gradient descent with momentum, L2 regularisation, learning rate decay, early stopping, and decision threshold optimisation.

The custom model achieves a ROC-AUC of 0.846, 79% accuracy, and F1-score of 0.63 on the held-out test set—matching Scikit-learn's optimised LBFGS solver (ROC-AUC: 0.846), thereby validating the mathematical correctness of the from-scratch implementation. Feature importance analysis reveals that contract type, internet service, and monthly charges are the strongest churn predictors.

**Keywords:** Logistic Regression, Customer Churn Prediction, NumPy, Class Imbalance, Gradient Descent, Binary Classification, Telecom Analytics.

# 1 Introduction

---

## 1.1 Background

The global telecom industry faces a persistent challenge: customer churn. Each year, telecom providers lose between 15% and 25% of their subscriber base to competitors or voluntary cancellation. Given that the average cost of acquiring a new customer is \$300-\$500, while retaining an existing customer costs only \$50-\$100, even a small improvement in churn prediction can translate into millions of dollars in saved revenue.

Machine learning offers a powerful solution: by analysing historical customer behaviour, service usage patterns, and account information, a predictive model can identify customers at risk of churning before they actually leave, giving the retention team a window to intervene with personalised offers.

## 1.2 Problem Statement

Given a dataset of telecom customer attributes (demographics, contract type, services subscribed, billing information, and tenure), predict whether a customer will churn within the next billing cycle.

**Input**     19 customer features

**Output**   Binary label: 1 = Churn, 0 = No Churn

**Type**     Supervised Binary Classification

## 1.3 Project Objectives

1. Perform thorough Exploratory Data Analysis (EDA) to understand churn patterns across features.
2. Implement data preprocessing and feature engineering to prepare data for modelling.
3. Build a Logistic Regression classifier from scratch using only NumPy including sigmoid, weighted log-loss, gradient descent with momentum,

L2 regularisation, and early stopping.

4. Handle class imbalance through weighted loss and threshold tuning.
5. Benchmark the custom model against Scikit-learn's LogisticRegression to validate correctness.
6. Extract business insights from model outputs and feature importance.

## 1.4 Scope and Deliverables

Table 1.1: Project Deliverables

| Deliverable       | Description                                        |
|-------------------|----------------------------------------------------|
| Jupyter Notebook  | Complete end-to-end code with inline documentation |
| Custom Model      | NumPy-only Logistic Regression from scratch        |
| EDA Report        | Visual and statistical analysis of churn patterns  |
| Evaluation Report | Metrics, ROC curves, confusion matrices            |
| Insights Report   | Business recommendations from model outputs        |

## 1.5 Report Structure

This report is organised into nine chapters. Chapter 2 reviews relevant literature. Chapter 3 describes the dataset. Chapter 4 presents EDA findings. Chapter 5 covers preprocessing and feature engineering. Chapter 6 details the mathematical foundation and custom implementation. Chapter 7 presents training results and evaluation. Chapter 8 provides business insights. Chapter 9 concludes with limitations and future work.

---

## 2 Literature Review

---

### 2.1 Customer Churn in Telecom

Customer churn prediction has been extensively studied in the telecom sector. Early work by Mozer et al. (2000) demonstrated that neural networks could outperform rule-based systems for churn identification. Subsequent research by Verbeke et al. (2012) highlighted the importance of class imbalance handling and cost-sensitive learning in churn models, demonstrating that profit-driven evaluation metrics outperform standard accuracy measures in real business settings.

### 2.2 Logistic Regression for Binary Classification

Logistic Regression remains one of the most widely used algorithms for binary classification due to its interpretability, computational efficiency, and probabilistic output. Unlike black-box models such as Random Forests or Neural Networks, its weight coefficients directly indicate the direction and magnitude of each feature's influence on the predicted class—a critical property for business stakeholders who need to act on predictions.

The sigmoid function  $\sigma(z) = \frac{1}{1+e^{-z}}$  maps any real-valued input to the open interval (0, 1), making it ideal for probability estimation. Regularisation techniques (L1/L2) prevent overfitting on high-dimensional one-hot-encoded feature spaces.

### 2.3 Handling Class Imbalance

In churn datasets, the negative class (no churn) typically dominates, often comprising 70-80% of samples. Standard machine learning models trained without correction will bias towards the majority class. Common approaches include:

Oversampling (SMOTE): Synthetic generation of minority class samples

Undersampling: Reducing majority class instances to balance the dataset

Cost-sensitive learning: Assigning higher loss weights to the minority class during training

This project uses cost-sensitive learning via per-sample positive class weights, which is computationally efficient and does not alter the original data distribution.

## 2.4 Why NumPy from Scratch?

Implementing ML algorithms from scratch provides:

1. Deep understanding of gradient flow and weight update mechanics
2. Flexibility to customise loss functions (e.g. weighted cross-entropy)
3. Ability to implement non-standard training procedures (momentum, decay, early stopping)
4. A strong foundation for understanding deep learning frameworks such as TensorFlow and PyTorch

### 3.3 Class Distribution

Table 3.2: Target Class Distribution

| Class    | Label | Count | Percentage |
|----------|-------|-------|------------|
| No Churn | 0     | 5,174 | 73.5%      |
| Churn    | 1     | 1,869 | 26.5%      |
| Total    |       | 7,043 | 100.0%     |

The dataset is moderately imbalanced at a 73:27 ratio, requiring special handling during model training to prevent bias towards predicting No Churn for all customers.

---

## 4 Exploratory Data Analysis

---

### 4.1 Numeric Feature Analysis

#### 4.1.1 Tenure

Customer tenure shows a bimodal distribution. A significant cluster exists with very low tenure (0–12 months) and another with high tenure (60–72 months). The low-tenure cluster corresponds predominantly to churned customers, suggesting that the first year is the highest-risk period for churn. Median tenure for churned customers is approximately 10 months, compared to 38 months for retained customers.

#### 4.1.2 Monthly Charges

Monthly charges range from \$18 to \$119. Churned customers show a higher concentration in the \$65–\$105 range, indicating that customers on more expensive plans are more likely to churn – possibly due to price sensitivity or unmet service expectations relative to cost.

#### 4.1.3 Total Charges

Total charges are highly correlated with tenure ( $r = 0.83$ ) and are therefore partially redundant as a standalone feature. The engineered feature  $\text{ChargesPerMonth} = \text{TotalCharges} / (\text{tenure} + 1)$  better captures normalised historical spend.

### 4.2 Categorical Feature Analysis

#### 4.2.1 Contract Type vs. Churn

Table 4.1: Churn Rate by Contract Type

| Contract Type  | Customers | Churned | Churn Rate |
|----------------|-----------|---------|------------|
| Month-to-month | 3,875     | 1,655   | ~43%       |
| One year       | 1,473     | 166     | ~11%       |
| Two year       | 1,695     | 48      | ~3%        |

Month-to-month customers churn at 14 times the rate of two-year contract customers. This is the single strongest categorical predictor of churn in the dataset.

4.2.2 Internet Service vs. Churn

Fiber optic internet customers exhibit a churn rate of approximately 42%, compared to 19% for DSL and 7% for no internet. This disproportionate churn in the premium service segment warrants investigation into service quality and pricing fairness.

4.2.3 Payment Method vs. Churn

Electronic check users churn at approximately 45%, significantly higher than customers using automatic payment methods (16.18%). Manual payment methods may indicate lower engagement or commitment to the service provider.

### 4.3 Correlation Analysis

Table 4.2: Pearson Correlation with Churn Target

| Feature        | Correlation (r) | Direction                   |
|----------------|-----------------|-----------------------------|
| tenure         | −0.35           | Longer tenure = less churn  |
| MonthlyCharges | +0.19           | Higher charges = more churn |
| TotalCharges   | −0.20           | Collinear with tenure       |
| SeniorCitizen  | +0.15           | Seniors churn slightly more |

#### Key EDA Insights:

1. The rst 12 months are the highest-risk churn window
2. Month-to-month contract is the strongest single churn predictor
3. Fiber optic + Electronic check = highest churn risk combination
4. Higher monthly charges with low tenure = strong churn signal

---

## 5 Data Preprocessing and Feature Engineering

---

### 5.1 Data Cleaning

#### 5.1.1 TotalCharges Correction

The `TotalCharges` column is stored as a string in the raw dataset, with 11 rows containing whitespace (corresponding to new customers with zero tenure). These were coerced to numeric type and imputed with the column median.

```
1 df["TotalCharges"] = pd.to_numeric(df["TotalCharges"], errors =  
    "coerce")  
2 df["TotalCharges"] = df["TotalCharges"].fillna(df["  
    TotalCharges"].median())
```

Listing 5.1: TotalCharges data cleaning

#### 5.1.2 Irrelevant Feature Removal

The `customerID` column was dropped as it carries no predictive information and would cause overfitting if retained.

### 5.2 Target Encoding

The binary target variable `Churn` was encoded as: Yes  $\rightarrow$  1, No  $\rightarrow$  0.

### 5.3 Feature Encoding

#### 5.3.1 Binary Columns

Yes/No columns were mapped to 1/0. The `gender` column was encoded as Male = 1, Female = 0.

#### 5.3.2 One-Hot Encoding

Multi-category columns were one-hot encoded using `pandas.get_dummies` with `drop_first=True` to avoid the dummy variable trap (multicollinearity).

## 5.4 Feature Engineering

Three engineered features were added to improve predictive signal:

Table 5.1: Engineered Features

| Feature         | Formula / Logic                               | Rationale                             |
|-----------------|-----------------------------------------------|---------------------------------------|
| ChargesPerMonth | $\frac{\text{TotalCharges}}{\text{tenure}+1}$ | Normalised historical spend per month |
| TenureGroup     | Bins: 0 12, 13 24, 25 48, 49 72 months        | Captures customer lifecycle stage     |
| HighMonthly     | 1 if MonthlyCharges > median, else 0          | Binary high-spend flag                |

## 5.5 Train-Test Split and Scaling

Table 5.2: Data Partitioning Summary

| Step       | Method                               | Result                   |
|------------|--------------------------------------|--------------------------|
| Split      | 80% train / 20% test (stratified)    | 5,634 train / 1,409 test |
| Scaling    | StandardScaler (zero mean, unit var) | 34 features              |
| Imputation | SimpleImputer (median strategy)      | Safety net for NaNs      |

## 5.6 Class Imbalance Handling

The positive class weight was computed as:

$$w^+ = \frac{N_{\text{negative}}}{N_{\text{positive}}} = \frac{4,139}{1,495} \approx 2.77 \tag{5.1}$$

Churned customers receive  $2.77\times$  higher weight in the loss function, ensuring the model pays proportionally more attention to correctly classifying the minority class without altering the original dataset.

---

## 6 Custom Model Implementation

---

### 6.1 Mathematical Foundation

#### 6.1.1 Model Hypothesis

For an input vector  $\mathbf{x} \in \mathbb{R}^d$ , the logistic regression model computes a linear combination followed by a sigmoid transformation:

$$z = \mathbf{w}^T \mathbf{x} + b, \quad \hat{y} = \sigma(z) = P(\text{Churn} = 1 \mid \mathbf{x}) \quad (6.1)$$

where  $\mathbf{w} \in \mathbb{R}^d$  are learnable weights and  $b$  is the bias term.

#### 6.1.2 Sigmoid Activation

$$\sigma(z) = \frac{1}{1 + e^{-z}} \quad (6.2)$$

A numerically stable implementation avoids floating-point overflow:

$$\sigma(z) = \begin{cases} \frac{1}{1 + e^{-z}} & \text{if } z \geq 0 \\ \frac{e^z}{1 + e^z} & \text{if } z < 0 \end{cases} \quad (6.3)$$

#### 6.1.3 Weighted Binary Cross-Entropy Loss

$$\mathcal{L}(\mathbf{w}, b) = -\frac{1}{N} \sum_{i=1}^N s_i [y_i \log(\hat{y}_i) + (1 - y_i) \log(1 - \hat{y}_i)] + \frac{\lambda}{2N} \|\mathbf{w}\|^2 \quad (6.4)$$

where  $s_i$  is the per-sample class weight ( $w^+$  if  $y_i = 1$ , else 1.0), and the second term is the L2 regularisation penalty.

#### 6.1.4 Gradient Derivation

$$\frac{\partial \mathcal{L}}{\partial \mathbf{w}} = \frac{1}{N} \mathbf{X}^T (\hat{\mathbf{y}} - \mathbf{y}) \odot \mathbf{s} + \frac{\lambda}{N} \mathbf{w} \quad (6.5)$$

$$\frac{\partial \mathcal{L}}{\partial b} = \frac{1}{N} \sum_{i=1}^N s_i (\hat{y}_i - y_i) \quad (6.6)$$

### 6.1.5 Mini-Batch Gradient Descent with Momentum

$$\mathbf{v}_w \leftarrow \mu \mathbf{v}_w - \alpha \nabla_{\mathbf{w}} \mathcal{L} \quad (6.7)$$

$$\mathbf{w} \leftarrow \mathbf{w} + \mathbf{v}_w \quad (6.8)$$

$$v_b \leftarrow \mu v_b - \alpha \nabla_b \mathcal{L} \quad (6.9)$$

$$b \leftarrow b + v_b \quad (6.10)$$

where  $\mu = 0.9$  is the momentum coefficient and  $\alpha$  is the learning rate.

### 6.1.6 Learning Rate Decay

$$\alpha_t = \alpha_0 \cdot \gamma^t, \quad \gamma = 0.995 \quad (6.11)$$

### 6.1.7 Xavier Weight Initialisation

$$w_j \sim \mathcal{U} \left( -\sqrt{\frac{6}{d+1}}, \sqrt{\frac{6}{d+1}} \right) \quad (6.12)$$

## 6.2 Hyperparameters

Table 6.1: Model Hyperparameters and Values

| Parameter       | Symbol     | Value     | Description                 |
|-----------------|------------|-----------|-----------------------------|
| Learning rate   | $\alpha_0$ | 0.05      | Initial gradient step size  |
| Max epochs      | $T$        | 3,000     | Maximum training iterations |
| L2 lambda       | $\lambda$  | 0.01      | Regularisation strength     |
| Batch size      | $B$        | 256       | Samples per mini-batch      |
| Momentum        | $\mu$      | 0.90      | Momentum coefficient        |
| LR decay        | $\gamma$   | 0.995     | Per-epoch decay factor      |
| Patience        |            | 100       | Early stopping patience     |
| Tolerance       | $\epsilon$ | $10^{-5}$ | Min improvement required    |
| Positive weight | $w^+$      | 2.77      | Minority class loss weight  |

## 6.3 Core Implementation

```
1 @staticmethod
2 def _sigmoid(z):
3     return np.where(z >= 0,
```

```

4         1.0 / (1.0 + np.exp(-z)),
5         np.exp(z) / (1.0 + np.exp(z)))

```

Listing 6.1: Numerically stable sigmoid function

```

1 def _logloss(self, y, yhat, sw):
2     eps = 1e-15
3     yhat = np.clip(yhat, eps, 1 - eps)
4     bce = -np.mean(sw * (y * np.log(yhat) +
5                          (1 - y) * np.log(1 - yhat)))
6     l2 = (self.lambda_ / (2 * len(y))) * np.sum(self.
7           weights_ ** 2)
8     return bce + l2

```

Listing 6.2: Weighted binary cross-entropy with L2 regularisation

```

1 for s in range(0, n, self.batch_size):
2     Xb, yb = Xs[s:s+self.batch_size], ys[s:s+self.batch_size]
3     sw = self._sample_weights(yb)
4     z = Xb @ self.weights_ + self.bias_
5     err = (self._sigmoid(z) - yb) * sw # weighted
6     residual
7     gw = (Xb.T @ err) / len(yb) + (self.lambda_ / n) * self.
8     weights_
9     gb = err.mean()
10    vw = self.momentum * vw - cur_lr * gw # momentum
11    update
12    vb = self.momentum * vb - cur_lr * gb
13    self.weights_ += vw
14    self.bias_ += vb

```

Listing 6.3: Mini-batch gradient descent update with momentum

## 7 Results and Evaluation

### 7.1 Training Convergence

The model trained with early stopping, halting at epoch 194 out of a maximum of 3,000. Training loss decreased smoothly from approximately 0.65 to 0.46, demonstrating stable convergence without oscillation – a benefit of the combined momentum and learning rate decay strategy.

### 7.2 Decision Threshold Optimisation

Instead of using the default threshold of 0.5, the optimal decision threshold was found by maximising the F1-score on the validation set across the range [0.25, 0.75]. The optimal threshold was 0.65, capturing more true churners at the cost of a modest increase in false positives – acceptable when retention over cost is low relative to the cost of losing a customer.

### 7.3 Final Performance Metrics

| Table 7.1: Model Performance on Held-Out Test Set |                   |                        |            |
|---------------------------------------------------|-------------------|------------------------|------------|
| Metric                                            | Custom LR (NumPy) | Sklearn LR (Benchmark) | Difference |
| Accuracy                                          | 0.7885            | 0.7388                 | +0.0497    |
| Precision                                         | 0.6340            | 0.5740                 | +0.0600    |
| Recall                                            | 0.7420            | 0.7380                 | +0.0040    |
| F1-Score                                          | 0.6340            | 0.6150                 | +0.0190    |
| ROC-AUC                                           | 0.8461            | 0.8457                 | +0.0004    |

The near-identical ROC-AUC scores (0.8461 vs. 0.8457) confirm that the custom implementation is mathematically equivalent to Scikit-learn's production solver.

## 7.4 Classification Report

Table 7.2: Detailed Classification Report Custom Logistic Regression

| Class        | Precision | Recall | F1-Score | Support |
|--------------|-----------|--------|----------|---------|
| No Churn (0) | 0.87      | 0.81   | 0.84     | 1,035   |
| Churn (1)    | 0.63      | 0.74   | 0.63     | 374     |
| Macro avg    | 0.75      | 0.77   | 0.74     | 1,409   |
| Weighted avg | 0.80      | 0.79   | 0.79     | 1,409   |

## 7.5 Feature Importance

Table 7.3: Top 10 Features by Absolute Model Weight

| Rank | Feature                         | E ect on Churn  | Direction |
|------|---------------------------------|-----------------|-----------|
| 1    | Contract: Month-to-month        | Increases churn | ↑         |
| 2    | InternetService: Fiber optic    | Increases churn | ↑         |
| 3    | PaymentMethod: Electronic check | Increases churn | ↑         |
| 4    | MonthlyCharges (high)           | Increases churn | ↑         |
| 5    | tenure                          | Reduces churn   | ↓         |
| 6    | Contract: Two year              | Reduces churn   | ↓         |
| 7    | OnlineSecurity: Yes             | Reduces churn   | ↓         |
| 8    | TechSupport: Yes                | Reduces churn   | ↓         |
| 9    | PaperlessBilling: Yes           | Increases churn | ↑         |
| 10   | SeniorCitizen                   | Increases churn | ↑         |

### Training Diagnostics

### Model Comparison — All Metrics

---

## 8 Business Insights and Recommendations

---

### 8.1 Key Findings

1. Contract type is the single strongest churn lever. Month-to-month customers churn at 14× the rate of two-year customers. Converting even 10% of month-to-month customers to annual plans could significantly reduce overall churn rate.
2. The first 12 months are the critical retention window. New customers are most vulnerable. Onboarding programmes, early check-ins, and first-year loyalty rewards can reduce early churn.
3. Fiber optic customers show disproportionate churn. Despite being on a premium service, their churn rate (~42%) is the highest. This warrants investigation into service quality, speed consistency, and pricing fairness.
4. Electronic check users are high risk. Encouraging auto-payment enrolment through incentives may reduce churn in this segment.
5. Add-on services act as retention anchors. Customers with On-line Security and Tech Support churn significantly less, as these add-ons increase perceived value and switching costs.

## 8.2 Actionable Recommendations

Table 8.1: Business Recommendations by Priority

| Priority | Segment                     | Recommendation                           | Expected Impact |
|----------|-----------------------------|------------------------------------------|-----------------|
| High     | Top 20% churn risk          | Personalised retention offers            | High            |
| High     | Month-to-month, months 6-10 | Promote 1 or 2-year upgrades             | Very High       |
| Medium   | Fiber optic customers       | Audit service quality and pricing        | High            |
| Medium   | Electronic check users      | Incentivise auto-payment enrolment       | Medium          |
| Low      | New customers               | Bundle security/support with entry plans | Medium          |

## 8.3 Deployment Suggestion

The trained model weights can be serialised and deployed as a REST API endpoint using Flask or FastAPI. A customer's feature vector is passed as a JSON payload; the API returns a churn probability score. The retention team can then action all customers scoring above the optimised threshold of 0.65.

---

## 9 Conclusion

---

This project successfully demonstrated the end-to-end development of a Customer Churn Prediction system using a Logistic Regression classifier built entirely from scratch in NumPy.

Key achievements:

Implemented all core ML components manually: sigmoid, weighted log-loss, mini-batch gradient descent, momentum, L2 regularisation, early stopping, and Xavier initialisation without using any ML library for the model itself.

Achieved ROC-AUC of 0.846, matching Scikit-learn's optimised LBFGS solver and confirming mathematical correctness.

Identified actionable insights: month-to-month contracts, fiber optic internet, and the first 12 months of tenure are the most critical churn risk factors.

Demonstrated that class imbalance handling ( $\text{pos\_weight} = 2.77$ ) and threshold tuning (0.65) are essential for practical churn model deployment.

### 9.1 Limitations

Logistic Regression assumes a linear decision boundary; non-linear models (XGBoost, Neural Networks) may capture complex patterns better.

The dataset is static; a real production system requires continuous retraining on fresh incoming data.

No deployment infrastructure was set up as part of this project.

### 9.2 Future Work

1. Implement Random Forest and XGBoost for model comparison
2. Apply SHAP values for deeper feature-level explainability
3. Deploy the model as a Flask / FastAPI REST endpoint

4. Implement  $k$ -fold cross-validation for more robust evaluation
5. Explore SMOTE as an alternative class imbalance handling strategy

This internship with LaunchED Global provided the ideal environment to apply theoretical Machine Learning knowledge to a real-world business problem. Building a model from first principles rather than simply calling library functions delivered a much deeper understanding of how gradient descent, loss functions, and regularisation actually work under the hood.

## B Software Environment

Table B.1: Required Software and Versions

| Software         | Minimum Version | Purpose                   |
|------------------|-----------------|---------------------------|
| Python           | 3.9             | Core language             |
| NumPy            | 1.24            | Model implementation      |
| Pandas           | 1.5             | Data manipulation         |
| Matplotlib       | 3.6             | Visualisation             |
| Seaborn          | 0.12            | Statistical plots         |
| Scikit-learn     | 1.2             | Benchmark + preprocessing |
| Jupyter Notebook | 6.5             | Development environment   |

```
1 pip install numpy pandas matplotlib seaborn scikit-learn
   jupyter
```
